LA3361**PLL FM MULTIPLEX STEREO DEMODULATOR****Use**

The LA3361, PLL FM multiplex stereo demodulator, is designed for low supply voltage-use appliance such as portable radio or car stereo.

Features

1. Wide supply voltage range down to low supply voltage: 3V min.
2. Operation of forced monaural (IF muting) or VCO stopping by only one pin.
Depending on supply voltage:
0.7V < V₉ < 2.1V: forced monaural (IF muting)
V₉ > 2.1V: VCO stopping
3. Good ripple rejection.
4. High level of lamp turning-on sensitivity: 7mV.
5. With separation control pin.
6. High gain.
7. Less current consumption: 8.5mA typical.

Maximum Ratings at Ta=25°C

			unit
Maximum Supply Voltage	V _{CCmax}	pin 6-7	16 V
		pin 1-7	16 V
Lamp Driving Current	I _L		40 mA
Allowable Power Dissipation	P _{dmax}	Ta ≤ 50°C	400 mW
Operation Temperature	T _{opr}		-20 to +70 °C
Storage Temperature	T _{stg}		-40 to +125 °C

Recommended Operating Conditions at Ta=25°C

			unit
Recommended Supply Voltage	V _{CC}		6 V
Input Signal Voltage	v _i		100 to 200 mV

Operating Characteristics at Ta=25°C, V_{CC}=6V, R_L=3.3kohms, input=100mV, L+R=90%, pilot=10%, f=1kHz:

			min	typ	max	unit
Quiescent Current	I _{cco}			8.5	12.0	mA
Input Resistance	r _i		15k	20k		ohm
Channel Separation			35	45		dB
Total Harmonic Distortion	THD	stereo, sub		0.2	0.7	%
Output Voltage	V _o	v _i =100mV	66	85	115	mV
Channel Balance				0.5	1.5	dB

Schematic Diagram of Pin 9 Control (Fig.10)

Proper cares in using the IC

(1) Pin 9-used control

Pin 9 is for stereo/monaural selection and VCO stop. When a voltage of less than 0.7V is applied to pin 9 or pin 9 is grounded or brought into the open state, the stereo (automatic) mode is entered. When a voltage of more than 2.1V is applied to pin 9, the VCO stops operating and the stereo indicator is prevented from malfunctioning. Therefore, no external measure against malfunction is required. When applying a voltage to pin 9, the following should be noted. An applied voltage of approximately 0.7V or 2.1V causes the internal transistors to enter the active region and hum or noise is liable to enter pin 9. Therefore, for example, the applied voltage must be set to an intermediate voltage such as 0V, 1.4V, 2.8V.

Schematic Diagram of Pin 9 Control (Fig.14)

When the VCO stop mode caused by application of a voltage to pin 9 is released, the stereo indicator may be turned ON momentarily. This phenomenon is liable to occur if the value of the capacitor across pins 10 and 11 is large ($C_{10-11} > 2$ to $3\mu\text{F}$). The reason for this is that if the VCO stop mode and forced monaural mode are released simultaneously when the C_{10-11} is charged with the pin 10 side being at "H" level at the VCO stop mode, the trigger circuit is turned ON until the C_{10-11} is discharged. This can be prevented by making the release of the forced monaural mode a little

later than that of the VCO stop mode. For this purpose, the C_9 is connected across pin 9 and GND as shown below so that the voltage on pin 9 drops slowly at the time of release.

$C_9 > 2C_{10-11}$ is a rule-of-thumb guide for the relation between C_9 and C_{10-11} which prevents the stereo indicator from being turned ON mistakenly.

(2) Loop filter capacitor C_{14-15}

When your set is designed with an input signal level of 250mV or greater, the C_{14-15} is $1\mu\text{F}$. The capture range tends to extend with the input level. When your set is designed with a high input signal level of 250mV or greater, your set is liable to be affected by high-frequency signals or noises. Therefore, the loop filter capacitor (across pins 14 and 15) should be made large to narrow the filter bandwidth. If $C_{14-15} = 1\mu\text{F}$ is used in your set with an input signal level of 250mV or greater, the capture range is made a little narrower and your set is hard to be affected by high-frequency signals.

(3) Phase compensation capacitor

(See Fig.8.)

A capacitor of 620pF is connected across pin 3 and GND to compensate the phase lead caused by the decoupling capacitor across pins 3 and 13 and the phase shift caused by the PLL. If no phase compensation capacitor is connected, the center of the separation characteristic plotted against the free-running frequency is off 19.00kHz and the margin for the free-running frequency drift and adjustment error becomes narrow. Therefore, phase compensation should be done.

(4) Separation control

The separation control is done to provide a single or double hump response in the separation vs. free-running frequency characteristic as shown on next page.

hump response side. For further details on separation, see the catalog of the LA3350.

As is obvious from the figure shown above, the double hump response has more margin for the free-running frequency drift. The double hump response is obtained by setting separation control resistance R_s to a rather large value. The separation varies with R_s as shown above and has peak point at $R_s \approx 380$ kohms give the single hump response. Separation control should be done at a point a little off this peak on the double
